RE: Underwood Creek Effluent Return Evaluation

SEH No.: 108425

Executive Summary

Waukesha Water Utility (WWU) is interested in determining the impact of a proposed effluent discharge on a 6,600-foot long segment of rehabilitated Underwood Creek watercourse, given that the rehabilitated channel has been designed for a base flow equal to 3 cubic feet per second (cfs). WWU has contracted with SEH to perform an evaluation of the impact of adding an approximate 20 cfs effluent return to the existing Underwood Creek base flow. The results of this evaluation are summarized herein, and address: (1) the rehabilitated main and low flow channel designs; (2) the hydraulic response of these rehabilitated channels to a range of discharges; and (3) the hydraulic, geomorphic and fisheries impacts of adding the effluent return to the Underwood Creek base flow.

Hydraulic conditions associated with a range of discharges were determined using a HEC-RAS hydraulic model of the rehabilitated main and low flow channels, extending from the confluence with the Menomonee River to Mayfair Road. HEC-RAS cross-sections were developed at riffle sections. This hydraulic evaluation demonstrated that the Phase 1 main and low flow channel designs, associated with the upstream 2,400 feet of rehabilitated watercourse, are appropriately designed for the desired capacities (200 cfs and 3 cfs, respectively). Preliminary Phase 2 channel dimensions are also provided that will require some adjustment during final design.

The proposed effluent return to Underwood Creek will have a negligible effect on the hydraulic and geomorphic conditions during average and peak discharge events. The addition of an effluent return to the Underwood Creek base flow (3 cfs) was evaluated over a range of modified low flow conditions, including 10 and 23 cfs, which resulted in water depths increasing between 0.15 and 0.80 feet (1.8 and 9.6 inches). Velocity increased from a negligible amount to a maximum of 1 foot per second (fps).

As a result of this evaluation, the following was concluded:

1. Current and Low Flow Channel Design: The current main and low flow channel design properly convey the design discharges (200 cfs and 3 cfs, respectively). Although,

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

- supplemental channel dimension definition will be needed during the completion of the Phase 2 final design, particularly within the steeper portions of the Phase 2 channel segment.
2. **Sediment Transport Considerations:** The majority of sediment transport tends to occur when the main channel is running full, a condition known as bankfull. For the current Underwood Creek channel design, this occurs when the discharge rate is approximately 200 cfs and shear stresses are approximately 1.0 pounds per square foot (lbs/sq.ft.). Sheer stresses that occur at discharges less than 50 cfs are relatively minor (less than 0.50 lbs/sq.ft.), and will not affect sediment transport. Therefore, the addition of an effluent return to Underwood Creek will not affect sediment transport.
 3. **Fisheries Considerations:** The most significant impact resulting from the effluent return is the water depth in the main channel outside the low flow channel. These variable water depths, however, are not expected to impact fish passage, since fish will move to the portion of the channel with a suitable water depth. A key parameter to fish passage is the minimum water depth, which is accommodated by the original low flow channel design. Should the low flow discharge increase, the resulting water depth outside the low flow channel will only enhance fish passage by creating additional flow within the channel cross-section.
 4. **Alternative Low Flow Channel Design Not Recommended:** An alternative low flow channel design was developed for comparative purposes, assuming a base flow equal to 23 cfs. However, the resulting change in channel hydraulics, compared to those provided by the current low flow channel design, does not justify developing the alternative low flow channel for the purpose of enhancing fish passage. In addition, given the anticipated fluctuations of the effluent return, a greater concern is that a modified low flow channel could be too large when the base flow is diminished, resulting in unacceptably low water depths.

Introduction

The Waukesha Water Utility (WWU) is proposing to use Great Lakes (Lake Michigan) water as their public water supply. Since the City of Waukesha is located west of the sub-continental divide, the Great Lakes Compact requires that this water be returned to Lake Michigan, minus an allowance for consumptive use. As a result, the WWU is investigating the discharge of treated wastewater effluent into Underwood Creek, in the vicinity of 124th Street and Bluemound Road, which would return water to the Great Lakes Basin that was previously pumped from Lake Michigan to the City of Waukesha. It is anticipated that the desired effluent diversion to Underwood Creek will have an Average Daily Flow (ADF) ranging from 17 to 20 cubic feet per second (cfs), which can also be interpreted as 7,600 to 9,000 gallons per minute (gpm), or 11 to 13 million gallons per day (mgd).

The Milwaukee Metropolitan Sewerage District (MMSD) has an ongoing *Underwood Creek Rehabilitation and Flood Management (R&FM) Project* that extends approximately 6,600 feet from the confluence with the Menomonee River to Mayfair Road (Highway 100). The Underwood Creek R&FM - Phase 1 Project is currently under construction, and extends approximately 2,400 feet downstream of Mayfair Road. The final design and construction of the Phase 2 Project, to occur in the future, will rehabilitate the remaining 4,400 feet of watercourse down to the Menomonee River confluence.

Given the above, the WWU is interested in determining the impact of the proposed effluent discharge on the rehabilitated Underwood Creek watercourse, given that the Phase 1

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

rehabilitated channel has been designed for a base flow equal to 3 cfs. Accordingly, WWU has contracted with SEH to perform an associated watercourse evaluation, with the objective of evaluating the impact of adding approximately 20 cfs to the existing Underwood Creek base flow. The results of this evaluation are summarized herein, and address: (1) the rehabilitated main and low flow channel designs for the Underwood Creek R&FM – Phase 1 and 2 Projects; (2) the hydraulic response of these rehabilitated channels to a range of discharges, extending from base flow to the main channel design capacity; and (3) the hydraulic, geomorphic and fisheries impacts of adding the desired effluent return to the Underwood Creek base flow.

Underwood Creek R&FM – Phase 1 and 2 Project Descriptions

Construction of watercourse improvements associated with the MMSD Underwood Creek R&FM – Phase 1 Project will result in the development of approximately 2,400 feet of rehabilitated stone-lined channel between Mayfair Road (Highway 100) and the Canadian Pacific Railway (CPR) Bridge, located just upstream of the Interstate 45 Bridge. These Phase 1 watercourse improvements, initiated in December 2008, are planned to be complete in June 2010, and include a single rehabilitated channel with an inner low flow channel that have design conveyance capacities equal to approximately 200 and 3 cfs, respectively. Rehabilitated main and low flow channel dimensions and bed slopes for Phase 1 were obtained from the project construction drawings provided in Attachment 1. In particular, Drawing GV-7 (Sheet 41) provides a typical cross-section at a riffle section, which illustrates the rehabilitated main channel with the inner low flow channel.

The MMSD Underwood Creek R&FM – Phase 2 Final Design and Construction Project will be completed in the future, which will rehabilitate approximately 4,200 feet of watercourse downstream of the Phase 1 Project. Preliminary Phase 2 channel bed slopes are defined in the MMSD *Underwood Creek R&FM Preliminary Engineering (PE) Design Report*, dated August 2006. Although the final design is not yet developed, it is likely that the Phase 2 rehabilitated main channel and interior low flow channel will have discharge capacities similar to those adopted for the Phase 1 Project. Phase 2 bed slopes were obtained from the preliminary drawings provided in Attachment 2. For analysis presented herein, the Phase 2 main and low flow channel dimensions were estimated using Manning's Equation, assuming uniform flow conditions.

Representative main and low flow channel dimensions and slopes, for the Phase 1 and 2 Projects, are presented in Table 1. Average bed slope was a key parameter value in the determination of the channel dimensions, which consist of a trapezoidal channel with bottom width, top width, depth and side slope. As presented on Table 1, the bed slope is generally flatter in Phase 1 Project segment (typically 0.194%). Near the upstream limit of the Phase 2 Project, over a length of 180 feet, the bed slope is much steeper (0.83%), gradually declining to 0.10% at the downstream limit of the project. As such, the main and low flow channel dimensions were adjusted to reflect the changing bed slope.

Basis for HEC-RAS Hydraulic Simulation

Hydraulic conditions associated with a range of discharges were determined using a HEC-RAS hydraulic model of the rehabilitated (Phase 1 and 2) main and low flow channels, extending from the confluence with the Menomonee River to Mayfair Road. HEC-RAS cross-sections were developed at riffle sections (pools sections were not considered). Information pertaining to this hydraulic evaluation is provided below.

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

1. Simulated Discharges: Seven sets of discharges were input to the HEC-RAS model in order to evaluate the hydraulic response for a range of flow conditions for the main and low flow channel. These discharges include 3 cfs (base flow) and 23 cfs (base flow discharge with an assumed 20 cfs ADF effluent diversion). Also, given previously developed design peak discharge events, it was determined that discharges resulting from land surface runoff events (50 cfs and greater) increase approximately 35 percent downstream of Station 147+50, which is located approximately 300 feet downstream of the CPR Railroad Bridge. It was assumed that smaller discharge events (less than 50 cfs) resulted primarily from interflow and groundwater inputs, and a 35 percent increase in discharge at Station 147+50 was not warranted for these events. Accordingly, the discharges used in the HEC-RAS hydraulic simulations are:
 - a. *Station 147+50 to 176+20:* 3, 5, 10, 23, 50, 100 and 200 cfs
 - b. *Station 110+50 to 147+50:* 3, 5, 10, 23, 70, 136 and 270 cfs.
2. HEC-RAS Cross-Sections: Representative HEC-RAS cross-sections, illustrating the main and low flow channels for the stations listed on Table 1, are provided on the exhibits described below. Each of these exhibits also presents seven water surface elevations (WSE) associated with the range of discharges presented above.
 - a. *Phase 1 Channel Cross-Sections* - Exhibits A-1 through A-5 present main and low flow channel cross-sections at Stations 172+00, 163+50, 157+00, 153+50 and 152+50, respectively, which can be located on the drawings included in Attachment 1.
 - b. *Phase 2 Channel Cross-Sections* - Exhibits B-1 through B-6 present main and low flow channel cross-sections at Stations 149+50, 147+50, 146+00, 133+40, 118+40 and 110+50, respectively, which can be located on the drawings included in Attachment 2.
3. HEC-RAS Channel Bed and WSE Profiles: Channel bed and WSE profiles for the discharges identified above are illustrated on Exhibit C, which also identifies the location of main channel stations referenced elsewhere. Evident from this exhibit are the variable channel bed slopes summarized on Table 1.
4. HEC-RAS Summary Output Table: Attachment 3 includes a tabular summary of HEC-RAS hydraulic output, which includes for each station and discharge (Q Total) the following hydraulic data: minimum channel elevation (Min Ch El), water surface elevation (W.S. Elev), average channel shear stress (Shear Chan), energy grade elevation (E.G. Elev), energy grade slope (E.G. Slope), channel velocity (Vel. Chnl), flow area, top width, and channel Froude number (Froude # Chl).
5. Station and River Mile References: Rehabilitated main and low flow channel information presented in Attachments 1 and 2 are referenced to the Rehabilitated Main Channel Baseline (RMCB) Stations, which are measured in feet from the confluence with the Menomonee River (Note: The RMCB Station at the Menomonee River confluence is equal to 7+00 feet). The HEC-RAS output provided in Attachment 3 is referenced to River Mile (RM), which is measured in miles from the Menomonee River confluence. Both sets of cross-section markers are provided in Table 1 for comparison purposes.

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

HEC-RAS Model Simulation Results Relative to the Current Main and Low Flow Channel Design

In regard to the HEC-RAS hydraulic simulation output referenced above, the following observations are noted, as related to the currently designed rehabilitated main channel and interior low flow channel.

1. Main Channel WSEs: As presented on Exhibits A-1 through B-6, the main channel dimensions summarized on Table 1 provide reasonable WSEs for the desired main channel discharge capacity (200 cfs upstream of Station 147+50 and 270 cfs downstream of Station 147+50). In particular:
 - a. *Phase 1 Dimensions* - Main channel dimensions provided for Phase 1 (currently under construction) provide a WSE near the top of bank (typically within one foot), as illustrated on Exhibits A-1 through A-5.
 - b. *Phase 2 Dimensions* – In general, preliminary main channel dimensions provided for Phase 2 also provide a WSE near the top of bank, as illustrated on Exhibits B-1 through B-6. However, additional analysis is recommended during the completion of the future final main channel design in order to provide a conveyance capacity closer to the desired main channel discharges, particularly along the steeper portions of the channel (Station 133+40 to 149+50).
2. Low Flow Channel WSEs: As presented on Exhibits A-1 though B-6, the low flow channel dimensions summarized on Table 1 also provide reasonable WSEs for the desired low flow discharge capacity (3 cfs). In particular:
 - a. *Phase 1 Dimensions* – Low flow channel dimensions provided for Phase 1 (currently under construction) provide a WSE near the top of the low flow channel bank (typically within 0.2 feet), as illustrated on Exhibits A-1 through A-5.
 - b. *Phase 2 Dimensions* – In general, preliminary low flow channel dimensions provided for Phase 2 also provide a WSE near the top of bank, as illustrated on Exhibits B-1 through B-6. However, additional analysis is again recommended during the completion of the future final low flow channel design in order to provide a conveyance capacity closer to the desired low flow channel discharge (3 cfs). Of particular importance is the segment of low flow channel (Station 146+00 to 149+50) where the WSE resulting from 3 cfs exceeds the top of the low flow channel by approximately 0.05 feet.
3. Channel Shear Stresses: The majority of sediment transport will tend to occur when the main channel is running full, a condition known as bankfull. The shear stress on the channel bed at bankfull appears adequate (typically around 1 lbs/sq. ft., as shown in Attachment 3). Sheer stresses that occur at discharges less than 50 cfs (70 cfs downstream of Station 147+50), as presented in Attachment 3, are relatively minor (less than 0.50 lbs/sq.ft.), which will not affect sediment transport.

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

Anticipated Impact Resulting from the Proposed Effluent Return

In regard to the anticipated impact of the proposed effluent return on the rehabilitated Underwood Creek channel, the following observations are noted:

1. **Impact on Underwood Creek Discharges:** The following is noted regarding the impact of the proposed effluent return on Underwood Creek discharges.
 - a. *Average and Peak Discharge Events* - There is general agreement that a proposed effluent return to Underwood Creek equal to 20 cfs or less (ADF) will have a negligible effect on the hydraulic and geomorphic conditions during average and peak discharge events. This lack of effect is due to the short durations of average and peak discharge events, and the relatively minor percent increase in overall flow resulting from the effluent return.
 - b. *Base Flow Events* - The addition of an effluent return to the Underwood Creek base flow (3 cfs) could have a relatively significant impact on the resulting main channel discharge rate, recognizing that the actual effluent return value is dependent on weather and operational conditions. For instance, it is noted that a 20 cfs effluent return could experience an operational diurnal fluctuation that would cause the instantaneous flow rate to range from approximately 6 cfs to 28 cfs during a typical 24 hour period. Weather conditions that could affect the effluent return rate include wet weather patterns that induce infiltration and inflow (I&I) to the sanitary collection system; and warm and dry weather conditions that reduce I&I, while increasing outdoor watering. As a result, it is best to evaluate the impact of an effluent return on Underwood Creek over a range of potential discharge conditions, as presented in Attachment 3, which includes results from discharges equal to 3, 5, 10 and 23 cfs.
2. **Impact on Main Channel Hydraulics (Existing Design):** The following is noted regarding the impact on main channel hydraulics due to the addition of the effluent return, assuming a range of discharge conditions and the existing design of the main and low flow channel.
 - a. *Water Depth and Velocity Impacts* – Using the data provided in Attachment 3, Table 2 summarizes the WSEs, water depths and average velocities resulting from a range of base flow discharges, including 3, 10 and 23 cfs. Table 2 also presents the change in water depth and average velocity, assuming an increase in the base flow discharge from 3 cfs to 10 and 23 cfs. As presented on Table 2, the increase in water depth varies from 0.15 feet (1.8 inches) to 0.80 feet (9.6 inches). The average velocity varies from a slight reduction (-0.07 fps) to an increase equal to 1.04 fps.
 - b. *Water Depth Outside the Low Flow Channel* - As illustrated on Exhibits A-1 through B-6, the WSEs resulting from the 23 cfs discharge event (3 cfs base flow plus an assumed 20 cfs ADF effluent return) results in water depths in the main channel (outside the low flow channel) ranging from 0.33 to 0.78 feet (4.0 to 9.4 inches). Given the results summarized in Table 2, a channel discharge equal to 10 cfs would result in water depths (outside the low flow channel) ranging from 0.13 to 0.39 feet (1.6 to 4.7 inches).
 - c. *Geomorphic Impacts* – As provided in Attachment 3 and stated previously, average channel shear stresses associated with discharges less than 50 cfs (70 cfs downstream of Station 147+50) will not significantly contribute to sediment transport. Therefore, the

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

addition of the effluent return, given the above stated discharge range, will not impact sediment transport conditions in the rehabilitated Underwood Creek channel.

3. Impact on Fisheries: The following is noted regarding the anticipated impact on fisheries due to the effluent return.
 - a. Indicator Species - The indicator fish species for the rehabilitated Underwood Creek channel has been identified as Northern pike, a relatively weak swimming fish. For the purposes of evaluating water velocity in the low flow channel relative to the swimming capabilities of this fish species, an average maximum velocity ranging from 1.5 to 1.7 feet per second (fps) was used.
 - b. Average Channel Velocities - Average channel velocities reported in Attachment 3, for discharges equal to or less than 23 cfs, are generally less than the targeted velocity range for Northern Pike, indicating that the effluent return discharge will have minimal impact on upstream fish passage during base flow conditions.
 - c. Need for Additional Channel Design - It is noted, however, that certain portions of the rehabilitated channel, primarily located where the bed gradient is steeper downstream of the CPR Railroad Bridge, do exceed this desirable velocity range. In these cases, the dimensions and slope of the low flow channel will need further refinement in order to lower velocities and better accommodate fish passage. Also, appropriate placement of boulders in riffle sections and pools can also help mitigate the impact of these higher velocities on fish passage.
 - d. Water Depths Outside the Low Flow Channel – Perhaps the most significant impact of the effluent return is the water depth in the main channel outside the low flow channel, as described previously. These variable water depths, however, are not expected to impact fish passage, since fish will move to the portion of the channel with a suitable water depth. A key parameter to fish passage is the minimum water depth, which is accommodated by the original low flow channel design. Should the low flow discharge increase, the resulting water depth outside the low flow channel will only enhance fish passage by creating additional flow area within the channel cross-section.
4. Alternative Low Flow Channel Design: For comparative purposes, an alternative low flow channel design was developed to convey a 23 cfs base flow along the Phase 1 and 2 Project segments. The modified low flow channel dimensions were created using Manning's Equation and are also presented in Table 1. The following is noted regarding these modified low flow channel designs, which are not recommended because they would provide no additional benefit in comparison to the current low flow channel design.
 - a. Depths of Flow and Velocities - As presented on Table 1, the depths associated with these modified low flow channels are 1.50 feet in the Phase 1 channel segment, and 0.56 to 1.20 feet in the Phase 2 channel segment. Corresponding average channel velocities were 1.5 fps in the Phase 1 channel segment, and 1.0 to 2.1 fps in the Phase 2 channel segment.
 - b. Channel Bottom and Top Widths – The additional base flow was generally accommodated by developing a wider channel bottom, then by increasing channel depth as needed. In this manner, base flow velocities are kept at an acceptable range of values, given the associated increase in channel roughness and wetted perimeter.

Waukesha Water Utility
Underwood Creek Effluent Return Evaluation

- c. *Impact on Existing Main Channel Design* – The modified low flow channel designs provided in Table 1 will fit within the bottom of the existing main channel. An example (Phase 1) modified low flow channel is presented in Exhibit D. Similar modified channel cross-sections would be developed for the Phase 2 watercourse segment. In most instances, the top of the low flow channel would essentially merge directly into the bottom of the main channel.
 - d. *Necessity of Modified Low Flow Channel* – Given the above results, the velocities and shear stresses of the modified low flow channels, assuming a base flow equal to 23 cfs, will be similar to those provided using the existing low flow channel design. The principal difference will be the depth of flow, which will be slightly greater for the modified low flow channel during low flow events. However, this slight difference does not warrant redesigning the low flow channel for the purpose of enhancing fish passage. In addition, given the anticipated fluctuations of the effluent return, a greater concern is that the modified low flow channel could be too large when the base flow is diminished, resulting in unacceptably low water depths.
5. Effluent Return Benefits: The following is noted regarding the potential benefits associated with the development of an effluent return to the rehabilitated Underwood Creek watercourse, as currently designed.
- a. *Fisheries Benefit* – As stated previously, an increased water depth outside the low flow channel will enhance fish passage by creating additional flow area within the channel cross-section. It is acknowledged that fish will move to the portion of the main channel that has a suitable flow depth, and the key is to provide a minimum depth, which is accommodated by the previously designed low flow channel.
 - b. *Floodplain Hydration* – Having a higher low flow depth in the main channel will also slightly increase groundwater elevations in the floodplain in the vicinity of channel, which will improve hydration for the wetland plantings. The extent of this enhancement can not be determined without additional study.
 - c. *Other Biological Benefits* – It is generally acknowledged that a greater base flow discharge will provide enhanced aquatic habitat by virtue of there being more water in the main channel. The extent of this improvement, however, is beyond the scope of this evaluation, and is dependent on the water quality characteristics of the effluent return and the identified desirable aquatic species.
